

Extending partial permutations

Ben Brewster

ABSTRACT

Suppose $\Delta_1, \Delta_2, \Gamma_1, \Gamma_2$ are subset of the set of positive integers, $\bar{g} : \Delta_1 \rightarrow \Gamma_1$, $\bar{h} : \Delta_2 \rightarrow \Gamma_2$ and both \bar{g}, \bar{h} are bijections. The question posed was to find a set Ω of positive integers containing Δ_i, Γ_i for $i = 1, 2$ and $g, h \in \text{Sym } \Omega$ such that $\langle g, h \rangle$, the subgroup generated by g and h , is solvable and $g|_{\Delta_1} = \bar{g}$, $h|_{\Delta_2} = \bar{h}$.

The problem has its roots in complexity theory from theoretical computer science. The problem may be one that challenges the borders of NP-completeness.

Upon my arrival in Tübingen, I studied the test case: $\bar{g} : \begin{array}{l} 3 \rightarrow 2 \\ 2 \rightarrow 1 \\ 4 \rightarrow 4 \\ 5 \rightarrow 5 \end{array}$ and $\bar{h} : \begin{array}{l} 1 \rightarrow 1 \\ 2 \rightarrow 2 \\ 3 \rightarrow 4 \\ 4 \rightarrow 5 \end{array}$.

The talk will focus on two approaches—neither has yet been effective for a solution, but the ideas seemed to have potential.
